

## Outline

- Scalar nonlinear conservation laws
- Shocks and rarefaction waves
- Entropy conditions
- Finite volume methods
- Approximate Riemann solvers
- Lax-Wendroff Theorem

Reading: Chapter 11, 12

## Notes:

## Burgers' equation

Quasi-linear form:  $u_t + uu_x = 0$

The solution is constant on characteristics so each value advects at constant speed equal to the value...

## Notes:

## Burgers' equation

Equal-area rule:

The area "under" the curve is conserved with time,  
We must insert a shock so the two areas cut off are equal.

## Notes:

## Riemann problem for Burgers' equation

$$u_t + \left(\frac{1}{2}u^2\right)_x = 0, \quad u_t + uu_x = 0.$$

$$f(u) = \frac{1}{2}u^2, \quad f'(u) = u.$$

Consider Riemann problem with states  $u_\ell$  and  $u_r$ .

For **any**  $u_\ell, u_r$ , there is a weak solution consisting of this discontinuity propagating at speed given by the Rankine-Hugoniot jump condition:

$$s = \frac{\frac{1}{2}u_r^2 - \frac{1}{2}u_\ell^2}{u_r - u_\ell} = \frac{1}{2}(u_\ell + u_r).$$

**Note:** Shock speed is average of characteristic speed on each side.

**This might not be the physically correct weak solution!**

## Notes:

## Burgers' equation

The solution is constant on characteristics so each value advects at constant speed equal to the value...

## Notes:

## Weak solutions to Burgers' equation

$$u_t + \left(\frac{1}{2}u^2\right)_x = 0, \quad u_\ell = 1, \quad u_r = 2$$

Characteristic speed:  $u$  Rankine-Hugoniot speed:  $\frac{1}{2}(u_\ell + u_r)$ .

"Physically correct" rarefaction wave solution:

## Notes:

## Weak solutions to Burgers' equation

$$u_t + \left(\frac{1}{2}u^2\right)_x = 0, \quad u_\ell = 1, \quad u_r = 2$$

Characteristic speed:  $u$  Rankine-Hugoniot speed:  $\frac{1}{2}(u_\ell + u_r)$ .

Entropy violating weak solution:

R.J. LeVeque, University of Washington IPDE 2011, July 1, 2011 [FVMHP Sec. 11.13]

Notes:

## Weak solutions to Burgers' equation

$$u_t + \left(\frac{1}{2}u^2\right)_x = 0, \quad u_\ell = 1, \quad u_r = 2$$

Characteristic speed:  $u$  Rankine-Hugoniot speed:  $\frac{1}{2}(u_\ell + u_r)$ .

Another Entropy violating weak solution:

R.J. LeVeque, University of Washington IPDE 2011, July 1, 2011 [FVMHP Sec. 11.13]

Notes:

## Vanishing viscosity solution

We want  $q(x, t)$  to be the limit as  $\epsilon \rightarrow 0$  of solution to

$$q_t + f(q)_x = \epsilon q_{xx}.$$

This selects a unique weak solution:

- Shock if  $f'(q_\ell) > f'(q_r)$ ,
- Rarefaction if  $f'(q_\ell) < f'(q_r)$ .

Lax Entropy Condition:

A discontinuity propagating with speed  $s$  in the solution of a convex scalar conservation law is admissible only if  $f'(q_\ell) > s > f'(q_r)$ , where  $s = (f(q_r) - f(q_\ell))/(q_r - q_\ell)$ .

**Note:** This means characteristics must approach shock from both sides as  $t$  advances, not move away from shock!

R.J. LeVeque, University of Washington IPDE 2011, July 1, 2011 [FVMHP Sec. 11.13]

Notes:

R.J. LeVeque, University of Washington IPDE 2011, July 1, 2011 [FVMHP Sec. 11.13]

## Riemann problem for scalar nonlinear problem

$q_t + f(q)_x = 0$  with data

$$q(x, 0) = \begin{cases} q_l & \text{if } x < 0 \\ q_r & \text{if } x \geq 0 \end{cases}$$

Piecewise constant with a single jump discontinuity.

For Burgers' or traffic flow with quadratic flux, the Riemann solution consists of:

- Shock wave if  $f'(q_l) > f'(q_r)$ ,
- Rarefaction wave if  $f'(q_l) < f'(q_r)$ .

Five possible cases:

## Notes:

## Transonic rarefactions

**Sonic point:**  $u_s = 0$  for Burgers' since  $f'(0) = 0$ .

Consider Riemann problem data  $u_l = -0.5 < 0 < u_r = 1.5$ .

In this case wave should spread in **both directions**:

## Notes:

## Transonic rarefactions

Entropy-violating approximate Riemann solution:

$$s = \frac{1}{2}(u_l + u_r) = 0.5.$$

Wave goes **only to right**, no update to cell average on left.

## Notes:

## Transonic rarefactions

If  $u_\ell = -u_r$  then Rankine-Hugoniot speed is 0:

Similar solution will be observed with Godunov's method if entropy-violating approximate Riemann solver used.

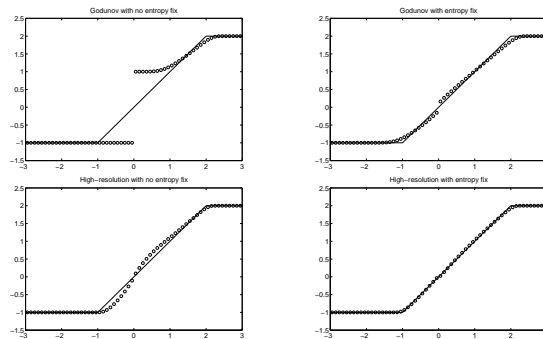

## Notes:

## Entropy-violating numerical solutions

Riemann problem for Burgers' equation at  $t = 1$

with  $u_\ell = -1$  and  $u_r = 2$ :

## Notes:

## Approximate Riemann solvers

For nonlinear problems, computing the **exact solution** to each Riemann problem may not be possible, or **too expensive**.

Often the nonlinear problem  $q_t + f(q)_x = 0$  is approximated by

$$q_t + A_{i-1/2} q_x = 0, \quad q_\ell = Q_{i-1}, \quad q_r = Q_i$$

for some choice of  $A_{i-1/2} \approx f'(q)$  based on data  $Q_{i-1}, Q_i$ .

Solve linear system for  $\alpha_{i-1/2}$ :  $Q_i - Q_{i-1} = \sum_p \alpha_{i-1/2}^p r_{i-1/2}^p$ .

**Waves**  $\mathcal{W}_{i-1/2}^p = \alpha_{i-1/2}^p r_{i-1/2}^p$  propagate with **speeds**  $s_{i-1/2}^p$ ,

$r_{i-1/2}^p$  are eigenvectors of  $A_{i-1/2}$ ,

$s_{i-1/2}^p$  are eigenvalues of  $A_{i-1/2}$ .

## Notes:

## Approximate Riemann solvers

$$q_t + \hat{A}_{i-1/2} q_x = 0, \quad q_\ell = Q_{i-1}, \quad q_r = Q_i$$

Often  $\hat{A}_{i-1/2} = f'(Q_{i-1/2})$  for some choice of  $Q_{i-1/2}$ .

In general  $\hat{A}_{i-1/2} = \hat{A}(q_\ell, q_r)$ .

**Roe conditions** for consistency and conservation:

- $\hat{A}(q_\ell, q_r) \rightarrow f'(q^*)$  as  $q_\ell, q_r \rightarrow q^*$ ,
- $\hat{A}$  diagonalizable with real eigenvalues,
- For conservation in wave-propagation form,

$$\hat{A}_{i-1/2}(Q_i - Q_{i-1}) = f(Q_i) - f(Q_{i-1}).$$

## Notes:

## Approximate Riemann solvers

For a **scalar** problem, we can easily satisfy the Roe condition

$$\hat{A}_{i-1/2}(Q_i - Q_{i-1}) = f(Q_i) - f(Q_{i-1}).$$

by choosing

$$\hat{A}_{i-1/2} = \frac{f(Q_i) - f(Q_{i-1})}{Q_i - Q_{i-1}}.$$

Then  $r_{i-1/2}^1 = 1$  and  $s_{i-1/2}^1 = \hat{A}_{i-1/2}$  (scalar!).

**Note:** This is the Rankine-Hugoniot shock speed.

$\implies$  shock waves are correct,  
rarefactions replaced by **entropy-violating shocks**.

## Notes:

## Approximate Riemann solver

$$Q_i^{n+1} = Q_i^n - \frac{\Delta t}{\Delta x} [\mathcal{A}^+ \Delta Q_{i-1/2} + \mathcal{A}^- \Delta Q_{i+1/2}].$$

For **scalar advection**  $m = 1$ , only one wave.

$\mathcal{W}_{i-1/2} = \Delta Q_{i-1/2} = Q_i - Q_{i-1}$  and  $s_{i-1/2} = u$ ,

$$\mathcal{A}^- \Delta Q_{i-1/2} = s_{i-1/2}^- \mathcal{W}_{i-1/2},$$

$$\mathcal{A}^+ \Delta Q_{i-1/2} = s_{i-1/2}^+ \mathcal{W}_{i-1/2}.$$

For scalar **nonlinear**: Use same formulas with

$\mathcal{W}_{i-1/2} = \Delta Q_{i-1/2}$  and  $s_{i-1/2} = \Delta F_{i-1/2} / \Delta Q_{i-1/2}$ .

Need to modify these by an **entropy fix** in the trans-sonic rarefaction case.

## Notes:

## Entropy fix

$$Q_i^{n+1} = Q_i^n - \frac{\Delta t}{\Delta x} [\mathcal{A}^+ \Delta Q_{i-1/2} + \mathcal{A}^- \Delta Q_{i+1/2}].$$

Revert to the formulas

$$\mathcal{A}^- \Delta Q_{i-1/2} = f(q_s) - f(Q_{i-1}) \quad \text{left-going fluctuation}$$

$$\mathcal{A}^+ \Delta Q_{i-1/2} = f(Q_i) - f(q_s) \quad \text{right-going fluctuation}$$

if  $f'(Q_{i-1}) < 0 < f'(Q_i)$ .

**High-resolution method:** still define wave  $\mathcal{W}$  and speed  $s$  by

$$\mathcal{W}_{i-1/2} = Q_i - Q_{i-1},$$

$$s_{i-1/2} = \begin{cases} (f(Q_i) - f(Q_{i-1})) / (Q_i - Q_{i-1}) & \text{if } Q_{i-1} \neq Q_i \\ f'(Q_i) & \text{if } Q_{i-1} = Q_i. \end{cases}$$

## Notes:

## Godunov flux for scalar problem

The Godunov flux function for the case  $f''(q) > 0$  is

$$F_{i-1/2}^n = \begin{cases} f(Q_{i-1}) & \text{if } Q_{i-1} > q_s \text{ and } s > 0 \\ f(Q_i) & \text{if } Q_i < q_s \text{ and } s < 0 \\ f(q_s) & \text{if } Q_{i-1} < q_s < Q_i. \end{cases}$$

$$= \begin{cases} \min_{Q_{i-1} \leq q \leq Q_i} f(q) & \text{if } Q_{i-1} \leq Q_i \\ \max_{Q_i \leq q \leq Q_{i-1}} f(q) & \text{if } Q_i \leq Q_{i-1}, \end{cases}$$

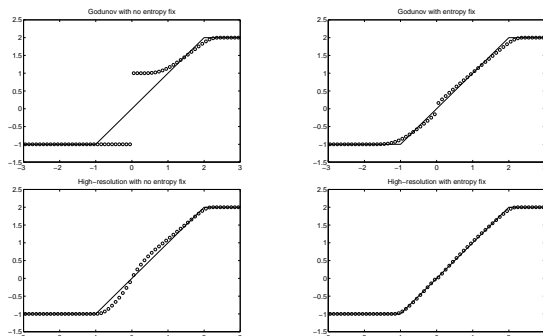

Here  $s = \frac{f(Q_i) - f(Q_{i-1})}{Q_i - Q_{i-1}}$  is the Rankine-Hugoniot shock speed.

## Notes:

## Entropy-violating numerical solutions

Riemann problem for Burgers' equation at  $t = 1$

with  $u_\ell = -1$  and  $u_r = 2$ :

## Notes:

## Entropy (admissibility) conditions

We generally require **additional conditions** on a weak solution to a conservation law, to pick out the unique solution that is physically relevant.

**In gas dynamics:** entropy is constant along particle paths for smooth solutions, **entropy can only increase** as a particle goes through a shock.

**Entropy functions:** Function of  $q$  that “behaves like” physical entropy for the conservation law being studied.

**NOTE:** Mathematical entropy functions generally chosen to **decrease** for admissible solutions, **increase** for **entropy-violating** solutions.

## Notes:

## Entropy functions

A scalar-valued function  $\eta : \mathbb{R}^m \rightarrow \mathbb{R}$  is a **convex function** of  $q$  if the **Hessian matrix**  $\eta''(q)$  with  $(i, j)$  element

$$\eta''_{ij}(q) = \frac{\partial^2 \eta}{\partial q^i \partial q^j}$$

is **positive definite** for all  $q$ , i.e., satisfies

$$v^T \eta''(q) v > 0 \quad \text{for all } q, v \in \mathbb{R}^m.$$

**Scalar case:** reduces to  $\eta''(q) > 0$ .

## Notes:

## Entropy functions

**Entropy function:**  $\eta : \mathbb{R}^m \rightarrow \mathbb{R}$    **Entropy flux:**  $\psi : \mathbb{R}^m \rightarrow \mathbb{R}$

chosen so that  $\eta(q)$  is convex and:

- $\eta(q)$  is conserved wherever the solution is smooth,

$$\eta(q)_t + \psi(q)_x = 0.$$

- Entropy decreases across an admissible shock wave.

**Weak form:**

$$\begin{aligned} \int_{x_1}^{x_2} \eta(q(x, t_2)) dx &\leq \int_{x_1}^{x_2} \eta(q(x, t_1)) dx \\ &+ \int_{t_1}^{t_2} \psi(q(x_1, t)) dt - \int_{t_1}^{t_2} \psi(q(x_2, t)) dt \end{aligned}$$

with equality where solution is smooth.

## Notes:

## Entropy functions

How to find  $\eta$  and  $\psi$  satisfying this?

$$\eta(q)_t + \psi(q)_x = 0$$

For smooth solutions gives

$$\eta'(q)q_t + \psi'(q)q_x = 0.$$

Since  $q_t = -f'(q)q_x$  this is satisfied provided

$$\psi'(q) = \eta'(q)f'(q)$$

**Scalar:** Can choose any convex  $\eta(q)$  and integrate.

**Example:** Burgers' equation,  $f'(u) = u$  and take  $\eta(u) = u^2$ .

Then  $\psi'(u) = 2u^2 \implies$  **Entropy function:**  $\psi(u) = \frac{2}{3}u^3$ .

## Notes:

## Weak solutions and entropy functions

The conservation laws

$$u_t + \left(\frac{1}{2}u^2\right)_x = 0 \quad \text{and} \quad (u^2)_t + \left(\frac{2}{3}u^3\right)_x = 0$$

both have the same quasilinear form

$$u_t + uu_x = 0$$

but have different weak solutions, **different shock speeds!**

**Entropy function:**  $\eta(u) = u^2$ .

A correct Burgers' shock at speed  $s = \frac{1}{2}(u_\ell + u_r)$  will have total mass of  $\eta(u)$  **decreasing**.

## Notes:

## Entropy functions

$$\begin{aligned} \int_{x_1}^{x_2} \eta(q(x, t_2)) dx &\leq \int_{x_1}^{x_2} \eta(q(x, t_1)) dx \\ &+ \int_{t_1}^{t_2} \psi(q(x_1, t)) dt - \int_{t_1}^{t_2} \psi(q(x_2, t)) dt \end{aligned}$$

comes from considering the vanishing viscosity solution:

$$q_t^\epsilon + f(q^\epsilon)_x = \epsilon q_{xx}^\epsilon$$

Multiply by  $\eta'(q^\epsilon)$  to obtain:

$$\eta(q^\epsilon)_t + \psi(q^\epsilon)_x = \epsilon \eta'(q^\epsilon) q_{xx}^\epsilon.$$

Manipulate further to get

$$\eta(q^\epsilon)_t + \psi(q^\epsilon)_x = \epsilon (\eta'(q^\epsilon) q_x^\epsilon)_x - \epsilon \eta''(q^\epsilon) (q_x^\epsilon)^2.$$

## Notes:

## Entropy functions

Smooth solution to viscous equation satisfies

$$\eta(q^\epsilon)_t + \psi(q^\epsilon)_x = \epsilon(\eta'(q^\epsilon)q^\epsilon_x)_x - \epsilon\eta''(q^\epsilon)(q^\epsilon_x)^2.$$

Integrating over rectangle  $[x_1, x_2] \times [t_1, t_2]$  gives

$$\begin{aligned} \int_{x_1}^{x_2} \eta(q^\epsilon(x, t_2)) dx &= \int_{x_1}^{x_2} \eta(q^\epsilon(x, t_1)) dx \\ &- \left( \int_{t_1}^{t_2} \psi(q^\epsilon(x_2, t)) dt - \int_{t_1}^{t_2} \psi(q^\epsilon(x_1, t)) dt \right) \\ &+ \epsilon \int_{t_1}^{t_2} [\eta'(q^\epsilon(x_2, t)) q^\epsilon_x(x_2, t) - \eta'(q^\epsilon(x_1, t)) q^\epsilon_x(x_1, t)] dt \\ &- \epsilon \int_{t_1}^{t_2} \int_{x_1}^{x_2} \eta''(q^\epsilon)(q^\epsilon_x)^2 dx dt. \end{aligned}$$

Let  $\epsilon \rightarrow 0$  to get result:

Term on third line goes to 0,

Term of fourth line is always  $\leq 0$ .

## Notes:

## Entropy functions

Weak form of entropy condition:

$$\int_0^\infty \int_{-\infty}^\infty [\phi_t \eta(q) + \phi_x \psi(q)] dx dt + \int_{-\infty}^\infty \phi(x, 0) \eta(q(x, 0)) dx \geq 0$$

for all  $\phi \in C_0^1(\mathbb{R} \times \mathbb{R})$  with  $\phi(x, t) \geq 0$  for all  $x, t$ .

Informally we may write

$$\eta(q)_t + \psi(q)_x \leq 0.$$

## Notes:

## Lax-Wendroff Theorem

Suppose the method is conservative and consistent with  $q_t + f(q)_x = 0$ ,

$$F_{i-1/2} = \mathcal{F}(Q_{i-1}, Q_i) \quad \text{with } \mathcal{F}(\bar{q}, \bar{q}) = f(\bar{q})$$

and Lipschitz continuity of  $\mathcal{F}$ .

If a sequence of discrete approximations converge to a function  $q(x, t)$  as the grid is refined, then this function is a weak solution of the conservation law.

**Note:**

Does not guarantee a sequence converges (need stability).

Two sequences might converge to different weak solutions.

Also need to satisfy an entropy condition.

## Notes:

## Sketch of proof of Lax-Wendroff Theorem

Multiply the conservative numerical method

$$Q_i^{n+1} = Q_i^n - \frac{\Delta t}{\Delta x} (F_{i+1/2}^n - F_{i-1/2}^n)$$

by  $\Phi_i^n$  to obtain

$$\Phi_i^n Q_i^{n+1} = \Phi_i^n Q_i^n - \frac{\Delta t}{\Delta x} \Phi_i^n (F_{i+1/2}^n - F_{i-1/2}^n).$$

This is true for all values of  $i$  and  $n$  on each grid.

Now sum over all  $i$  and  $n \geq 0$  to obtain

$$\sum_{n=0}^{\infty} \sum_{i=-\infty}^{\infty} \Phi_i^n (Q_i^{n+1} - Q_i^n) = -\frac{\Delta t}{\Delta x} \sum_{n=0}^{\infty} \sum_{i=-\infty}^{\infty} \Phi_i^n (F_{i+1/2}^n - F_{i-1/2}^n).$$

Use [summation by parts](#) to transfer differences to  $\Phi$  terms.

Notes:

## Sketch of proof of Lax-Wendroff Theorem

Obtain analog of weak form of conservation law:

$$\Delta x \Delta t \left[ \sum_{n=1}^{\infty} \sum_{i=-\infty}^{\infty} \left( \frac{\Phi_i^n - \Phi_i^{n-1}}{\Delta t} \right) Q_i^n + \sum_{n=0}^{\infty} \sum_{i=-\infty}^{\infty} \left( \frac{\Phi_{i+1}^n - \Phi_i^n}{\Delta x} \right) F_{i-1/2}^n \right] = -\Delta x \sum_{i=-\infty}^{\infty} \Phi_i^0 Q_i^0.$$

Consider on a sequence of grids with  $\Delta x, \Delta t \rightarrow 0$ .

Show that any limiting function must satisfy weak form of conservation law.

Notes:

## Analog of Lax-Wendroff proof for entropy

Show that the numerical flux function  $F$  leads to a

[numerical entropy flux](#)  $\Psi$

such that the following [discrete entropy inequality](#) holds:

$$\eta(Q_i^{n+1}) \leq \eta(Q_i^n) - \frac{\Delta t}{\Delta x} \left[ \Psi_{i+1/2}^n - \Psi_{i-1/2}^n \right].$$

Then multiply by test function  $\Phi_i^n$ , sum and use summation by parts to get discrete form of integral form of entropy condition.

$\implies$  If numerical approximations converge to some function, then the limiting function satisfies the entropy condition.

Notes:

## Entropy consistency of Godunov's method

For Godunov's method,  $F(Q_{i-1}, Q_i) = f(Q_{i-1/2}^\psi)$

where  $Q_{i-1/2}^\psi$  is the constant value  
along  $x_{i-1/2}$  in the Riemann solution.

Let  $\Psi_{i-1/2}^n = \psi(Q_{i-1/2}^\psi)$

Discrete entropy inequality follows from [Jensen's inequality](#):

The value of  $\eta$  evaluated at the average value of  $\tilde{q}^n$  is less than  
or equal to the average value of  $\eta(\tilde{q}^n)$ , i.e.,

$$\eta\left(\frac{1}{\Delta x} \int_{x_{i-1/2}}^{x_{i+1/2}} \tilde{q}^n(x, t_{n+1}) dx\right) \leq \frac{1}{\Delta x} \int_{x_{i-1/2}}^{x_{i+1/2}} \eta(\tilde{q}^n(x, t_{n+1})) dx.$$

## Notes:
